

Day 3: Overfitting and Generalization

Summer STEM: Machine Learning

Department of Electrical Engineering
NYU Tandon School of Engineering
Brooklyn, New York

August 5, 2020

Linear Regression

- What if we have multivariate data with \mathbf{x} being a vector?
- Ex: $\mathbf{x}_i = [x_{i1}, x_{i2}]^T$

$$\hat{y}_1 = w_0 + w_1 x_{11} + w_2 x_{12}$$

$$\hat{y}_2 = w_0 + w_1 x_{21} + w_2 x_{22}$$

$$\vdots$$

$$\hat{y}_N = w_0 + w_1 x_{N1} + w_2 x_{N2}$$

- The model can be written as $\hat{y}_i = [1 \quad x_{i1} \quad x_{i2}] \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$

Multilinear Regression

- In matrix-vector form

$$\begin{bmatrix} \hat{y}_1 \\ \hat{y}_2 \\ \vdots \\ \hat{y}_n \end{bmatrix} = \begin{bmatrix} 1 & x_{11} & x_{12} \\ 1 & x_{21} & x_{22} \\ \vdots & \vdots & \vdots \\ 1 & x_n & x_{n2} \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$$

- Solution remains the same $\mathbf{w} = (X^T X)^{-1} X^T Y$
- Exercise: open `demo_multilinear.ipynb`

Outline

- 1 Polynomial Regression
- 2 Train and Test Error, Overfitting
- 3 Regularization

Polynomial Fitting

- We have been using linear model to fit our data. But it doesn't work well every time
- Some data have more complex relation that cannot be fitted well using a straight line
 - Ex: Projectile motion, Coulomb's law, Exponential growth/decay, ...

- Linear model does not look like a good fit for this data
- Can we use some other model to fit this data?

Polynomial Fitting

- Can we use a polynomial to fit our data?
- Polynomial: A sum of different powers of a variable
 - Examples: $y = x^2 + 2$, $y = 5x^3 - 3x^2 + 4$

- New model: $f(x) = w_0 + w_1x + w_2x^2 + w_3x^3 + \dots$

Polynomial Fitting

- The process of fitting a polynomial is similar to linearly fitting multivariate data
- Recall the multivariable linear model
- $f(x) = w_0 + w_1x_1 + w_2x_2 + w_3x_3 + \dots$
 - Where $x_1, x_2, x_3 \dots$ are different features
- If we treat x^2 as our second feature, x^3 as our third feature, x^4 as our fourth feature.... We can use the same procedure in multivariate regression.

Polynomial Fitting

- Design matrix with the original feature:

$$X = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_N \end{bmatrix}$$

- Design matrix with augmented polynomial features:

$$\Phi(X) = \begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^D \\ 1 & x_2 & x_2^2 & \cdots & x_2^D \\ \vdots & & \ddots & & \vdots \\ 1 & x_N & x_N^2 & \cdots & x_N^D \end{bmatrix}$$

- For the polynomial fitting, we just added columns of features that are powers of the original feature

Demo: Fit a polynomial

- You are given the data set below with x and y values

- Try to fit the data using a polynomial with a certain degree
- Calculate mean square error between the sample y and your predicted y
- Try different polynomial degree and see if you can improve the mse
- Plot your polynomial over the data points

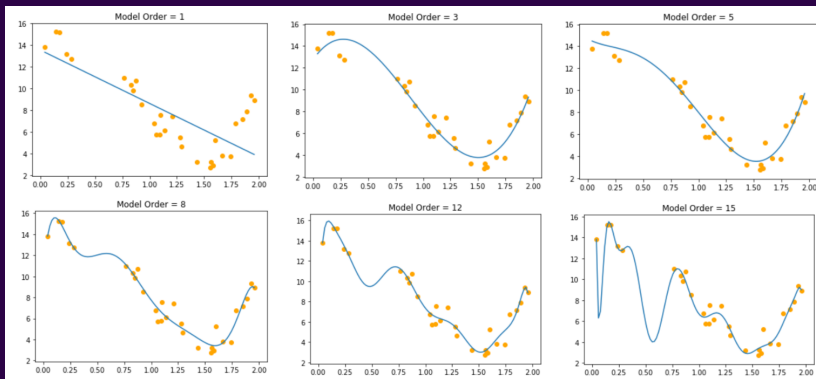

Outline

- 1 Polynomial Regression
- 2 Train and Test Error, Overfitting
- 3 Regularization

Overfitting

- We learned how to fit our data using polynomials of different order
- With a higher model order, we can fit the data with increasing accuracy
- As you increase the model order, at certain point it is possible find a model that fits your data perfectly (ie. zero error)
- What could be the problem?

Overfitting

■ Which of these model do you think is the best? Why?

Overfitting

- The problem is that we are only fitting our model using data that is given
- Data usually contains noise
- When a model becomes too complex, it will start to fit the noise in the data
- What happens if we apply our model to predict some data that the model has never seen before? It will not work well.
- This is called over-fitting

Overfitting

- Split the data set into a train set and a test set
- Train set will be used to train the model
- The test set will not be seen by the model during the training process
- Use test set to evaluate the model when a model is trained

- With the training and test sets shown, which one do you think is the better model now?

Train and Test Error

- Plot of train error and test error for different model order
- Initially both train and test error go down as model order increase
- But at a certain point, test error start to increase because of overfitting

Outline

- 1 Polynomial Regression
- 2 Train and Test Error, Overfitting
- 3 Regularization

How can we prevent overfitting without knowing the model order before-hand?

- **Regularization:** methods to prevent overfitting

How can we prevent overfitting without knowing the model order before-hand?

- **Regularization:** methods to prevent overfitting
 - We just covered regularization by model order selection

How can we prevent overfitting without knowing the model order before-hand?

- **Regularization:** methods to prevent overfitting
 - We just covered regularization by model order selection
- Is there another way? Talk among your classmates.

How can we prevent overfitting without knowing the model order before-hand?

- **Regularization:** methods to prevent overfitting
 - We just covered regularization by model order selection
- Is there another way? Talk among your classmates.
 - Solution: We can change our cost function.

Weight Based Regularization

- Looking back at the polynomial overfitting
- Notice that weight-size increases with overfitting

New Cost Function

$$J = \sum_{i=1}^N (y_i - \hat{y}_i)^2 + \lambda \sum_{j=1}^D (w_j)^2$$

- Penalize complexity by simultaneously minimizing weight values.
- We call λ a **hyper-parameter**
 - λ determines relative importance

Table 1.2 Table of the coefficients w^* for $M = 9$ polynomials with various values for the regularization parameter λ . Note that $\ln \lambda = -\infty$ corresponds to a model with no regularization, i.e., to the graph at the bottom right in Figure 1.4. We see that, as the value of λ increases, the typical magnitude of the coefficients gets smaller.

	$\ln \lambda = -\infty$	$\ln \lambda = -1.8$	$\ln \lambda = 0$
w_0^*	0.35	0.35	0.13
w_1^*	232.37	4.74	-0.05
w_2^*	-5321.83	-0.77	-0.06
w_3^*	48568.31	-31.97	-0.05
w_4^*	-231639.30	-3.89	-0.03
w_5^*	640042.26	55.28	-0.02
w_6^*	-1061800.52	41.32	-0.01
w_7^*	1042400.18	-45.95	-0.00
w_8^*	-557682.99	-91.53	0.00
w_9^*	125201.43	72.68	0.01

Tuning Hyper-parameters

- Motivation: never determine a hyper-parameter based on training data
- **Hyper-Parameter**: a parameter of the algorithm that is not a model-parameter solved for in optimization.
 - Ex: λ weight regularization value vs. model weights (\mathbf{w})
- Solution: split dataset into three
 - **Training set**: to compute the model-parameters (\mathbf{w})
 - **Validation set**: to tune hyper-parameters (λ)
 - **Test set**: to compute the performance of the algorithm (MSE)
